Experience

Senior Software Engineer at **Flagler Health** | *April 2025 - Current*

- Built and tuned AI systems across traditional predictive models and LLM-based agents, using LLMs as part of the model-tuning loop while maintaining distinct training, evaluation, context, and state-management workflows.
- Built reusable AI skills and workflows for engineering and operations, including structured context and state management that let agents operate against real application state rather than isolated prompts.
- Made AI-assisted implementation verifiable: encoded human-reviewed reasoning into repeatable checks, then used adversarial review and production-data validation to catch failures conventional tests missed.
- Helped build the voice-agent layer connecting patient context, scheduling, clinical workflows, and operational actions. Conversational AI, tied directly to care delivery.
- Connected the messy edges of healthcare: varied clinic data living across multiple EHR/EMR systems, claims, payer data, clinics, providers, and clinical workflows. Normalized it into a platform that users, automation, and AI can actually reason over.
- Fragmented clinic operations became structured, queryable primitives—the underlying data model and workflow rails for automation instead of another bespoke integration for every new use case.
- Built the Task/Playbook/Automation system as an execution layer for the platform, supporting broad event ingest, dynamic entity references, workflow logic, and downstream actions.
- Modeled payer coverage at the plan, clinic, capability, and procedure level, replacing ambiguous ad hoc SOP interpretation with deterministic, auditable logic that humans and AI can reuse.
- Connected clinical activity to billing and time tracking, tying enrollment, provider activity, EHR events, and work performed into trustworthy operational analytics.
- Established engineering guardrails for AI-native development, giving engineers reusable skills and verification patterns so the organization could increase AI adoption without simply increasing review burden.
- Designed foundational platform capabilities with a bias toward determinism: make the state explicit, the reasoning inspectable, and the resulting behavior reproducible by both humans and AI.

Senior Software Engineer at **Ria Health** | *August 2021 - April 2025*

- Directed a nationwide telehealth platform with intelligent scheduling and care coordination, managing state, license, credential, insurance-network, and phase-of-care constraints across a distributed provider network.
- Applied AI-driven demand and utilization forecasting across millions of clinical and operational data points to coordinate provider capacity and reduce patient wait times, including multi-provider care within a single session.
- Built patient-driven clinical assessment and digital therapeutics infrastructure, capturing longitudinal quantitative and qualitative data and integrating Bluetooth healthcare devices through SDKs and xAPI.
- Standardized device, engagement, assessment, and clinical data to power operational analytics, research, and real-time guidance for clinicians and patients under regulated data-handling requirements.
- Implemented automated clinical studies to capture patient feedback and outcomes, producing peer-reviewed research and feeding findings back into clinical and operational decisions.

Software Engineer at **Integral Ad Science** | *March 2021 - August 2021*

- Built production software for a high-scale advertising platform after transitioning from QA engineering into software development.
- Developed automated testing and reliability tooling across distributed systems, working closely with engineering teams to identify and resolve production issues.

Computer Science and Math Educator at **Leap Education** | *October 2015 - May 2019*

- Taught computer science and mathematics while developing technical curriculum and supporting students across a wide range of experience levels.

Education

Bachelors in Computer Science from **New York University**
